The screenshot shows the Fermilab website interface. On the left, there is a large graphic with the text "BEHIND THE SCIENCE" in a bold, black, serif font. The background of this graphic is a gradient of orange and yellow. To the right of the graphic is a satellite-style image of the Fermilab facility, showing several large circular and linear structures. Above the image is the text "Fermilab Accelerators". To the right of the image is a vertical navigation menu with the following items: Search, Help, Laboratory Index, What's New, The Laboratory, The Directorate, Particle Physics, Clickable Tour, Education, Visitors' Info, Cultural Events, Directories, and Fermilab At Work.

Fermilab Accelerators

SHOW AIRS: SAT 11/02 at 9am CT Your Host: David Finley

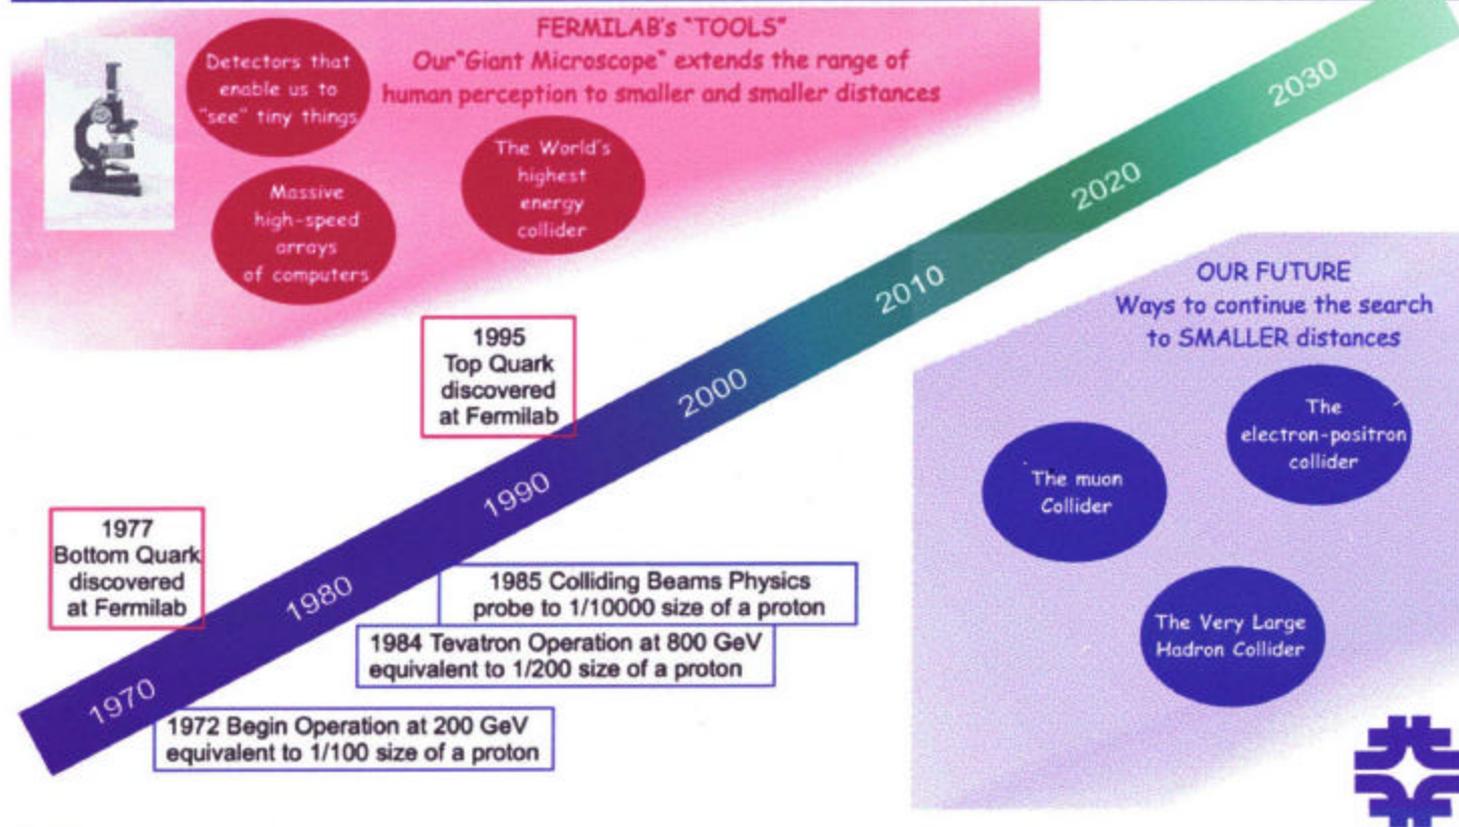

finley@fnal.gov

Accelerators

- Accelerators (Particle Accelerators)
 - today: particle beams for particle physics research
 - mostly use electrons and protons
 - and antiprotons and positrons, and mesons and neutrinos ...
 - not today: materials, medical, military (aka 3M), etc
- Why do this?
- A “few words about” Acceleration

Science at Fermilab

Fermilab advances the understanding of the fundamental nature of matter and energy by providing leadership and resources for qualified researchers to conduct basic research at the frontiers of high-energy physics

Accelerators - What are they good for?

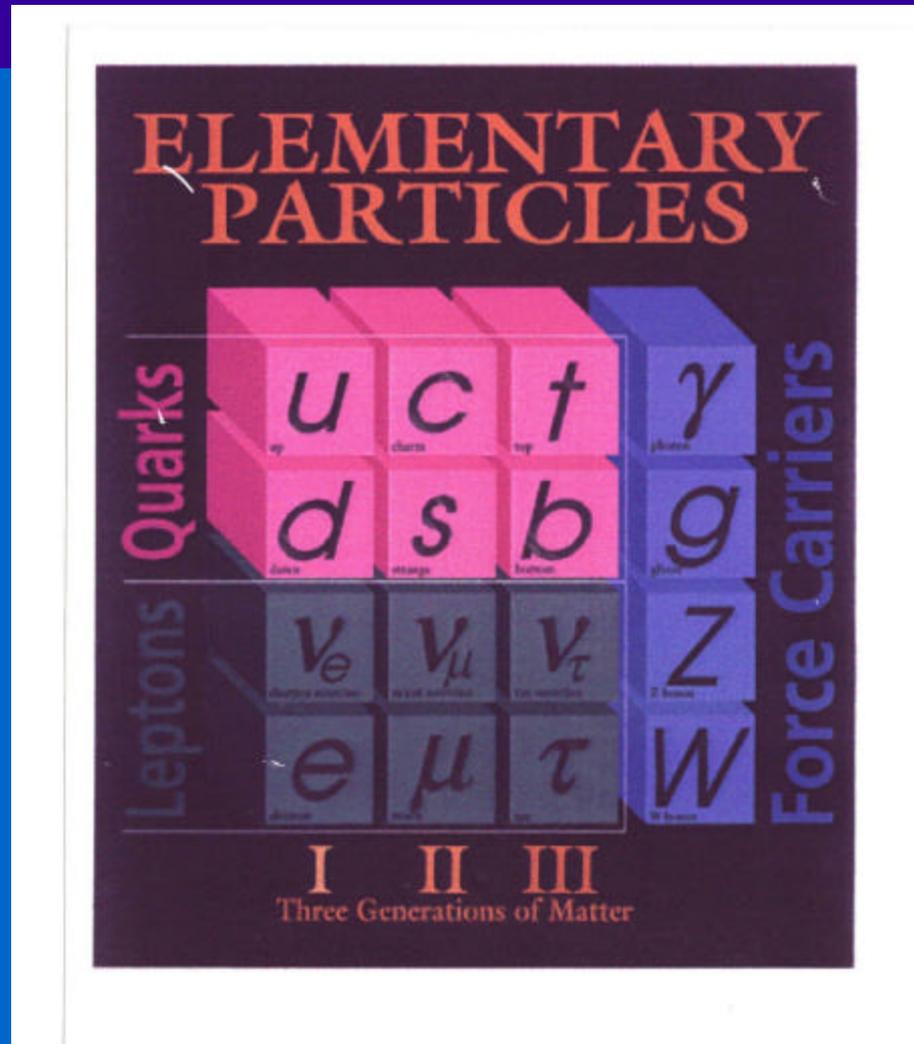

- Why do this? This = “particle physics”
 - Q1: What’s it all made of?
 - Q2: How does it all behave?
 - Q3: How do particles come by their mass?
 - Q4: How is it that we see more matter than antimatter?
 - And ... Q4++
 - So, how is it all distributed anyway?
 - Etc etc

f

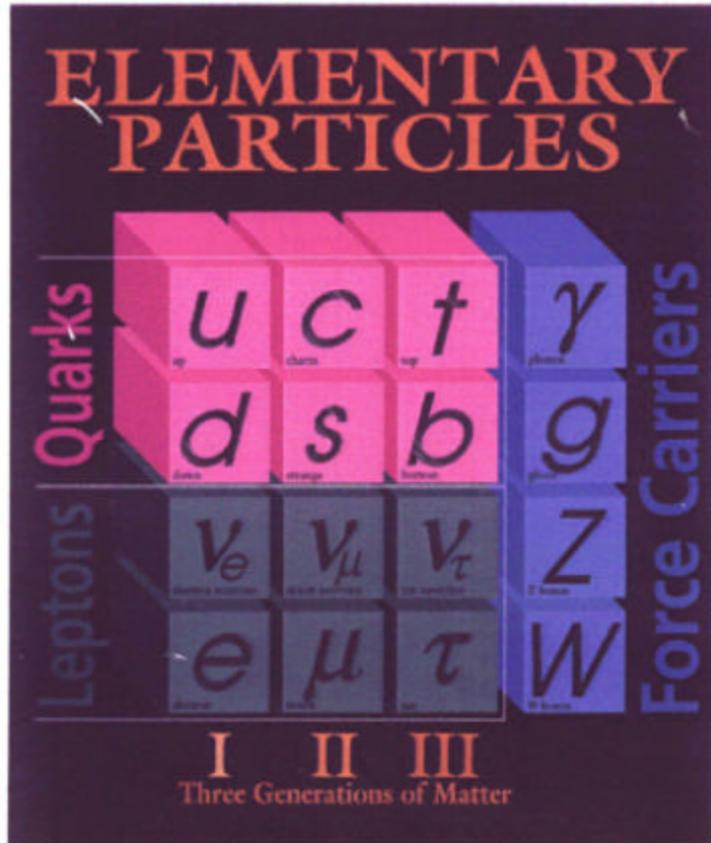

The Standard Model

f

Fermilab's Role (so far)

Fermilab has aided in the discovery of the:

- bottom quark (1977)
- top quark (1995)
- tau neutrino (2000)

Accelerators

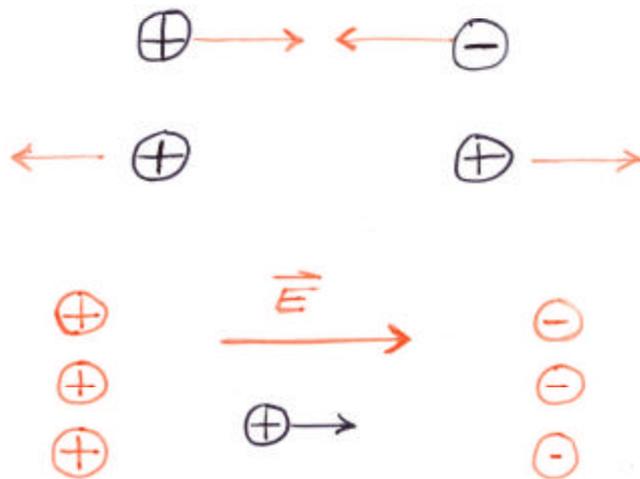

- Accelerators (Particle Accelerators)
 - today: particle beams for particle physics research
 - mostly use electrons and protons
 - and antiprotons and positrons, and mesons and neutrinos ...
 - not today: materials, medical, military (aka 3M), etc
- Why do this?
- Accelerator Basics <<< We Are Here

f

Accelerator Basics

- A Little from Maxwell, Newton, Lorentz
 - $\mathbf{F} = e \mathbf{E}$ and $\mathbf{F} = q (\mathbf{v}/c) \times \mathbf{B}$
 - $\mathbf{F} = d\mathbf{p}/dt$ and $\mathbf{p} = m \mathbf{v}$
- A Little Relativity from Einstein
 - $m = m_0 / \text{sqrt}(1 - \beta^2)$ with $\beta = v/c$
 - $E = m_0 c^2 + \text{Kinetic Energy}$ and $E = m c^2$
- A Little from Murphy (as in Murphy's Law)

Electric Force

$$\text{Force: } \vec{F} = (\text{charge}) \vec{E} = e\vec{E}$$

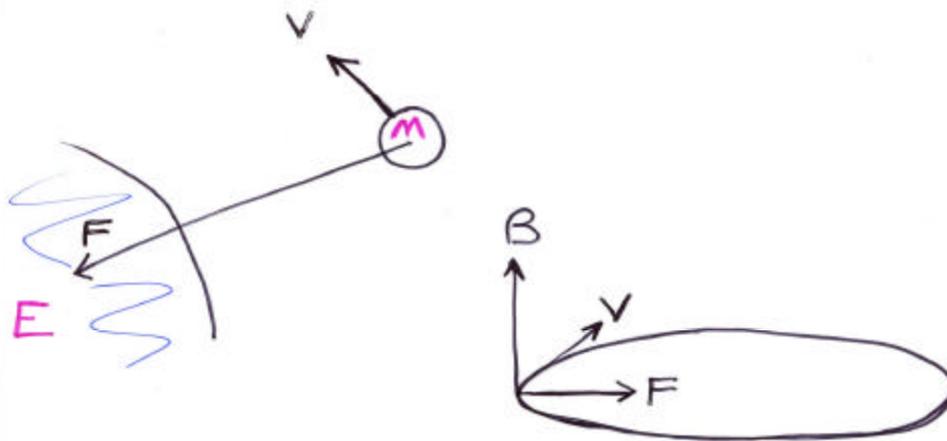

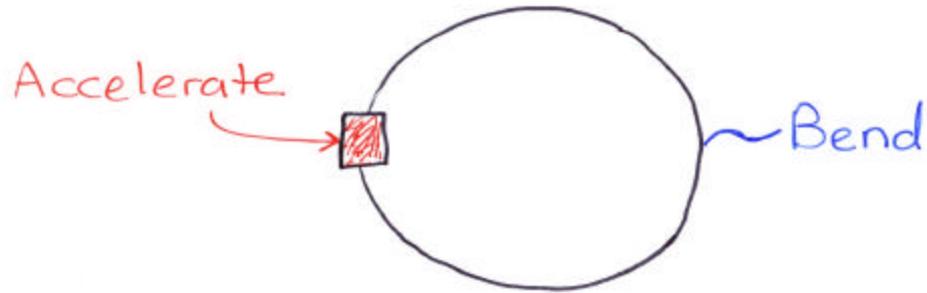

$$\text{Potential: } \text{Volts} = -E \times (\text{length moved})$$

$$\text{Energy: } E = (\text{charge})(\text{volt})$$

1 eV \rightarrow Energy gained by e
when pulled through 1 Volt

HiRise and Tevatron

- Insert 93-683-9 “HiRise and Tevatron” and pretend you are on the 15th floor giving a tour and read the following few slides

Overheard on the 15th Floor - 1

- So, if you look over there, you see a big orange building. That's where CDF is located. Collider Detector at Fermilab.
- And on a really clear day you can see the Sears Tower in Chicago over there.
- And directly opposite us over there is a blue building where the D-Zero detector is located.
- The Tevatron accelerator is located about 20 feet under the berm you see.
- We send the proton beam around the 6 kilometers of the Tevatron. It's inside a 7 cm diameter beam pipe with all the air removed. Otherwise the air molecules would eat up all the protons.
- The beam pipe goes through about 1000 superconducting magnets. The magnets have two jobs. Some of them keep the protons focussed so they don't wander off the central path. And the others bend the central path around in a circle so the beam keeps passing through the accelerating stations.

f

Overheard on the 15th Floor - 2

- Over there to the right is where the accelerating stations are located. They provide electric fields which are carefully timed to push the protons along to a higher energy. We use the same technology that radar is based on. For the rf in the Tevatron, the electric field flips its sign about 53 million times a second. So you have to be pretty careful with the timing.
- The beam goes around the 6 kilometers about 50,000 times a second. (47,713 if you are picky about numbers.) Every second!
- With an energy of about one trillion volts, or 1 TeV.
- That's the highest energy particle beam in the world. And will be until about 2006 when CERN starts up the LHC with its 7 TeV proton beams.
- In the Tevatron, a bunch of protons is about 40 microns in diameter at CDF or D-Zero. That's about the diameter of your hair.
- And a meter or so long. Like really long, really thin needles.

f

Overheard on the 15th Floor - 3

- There are about 100 billion protons in a bunch.
- And we collide it with an antiproton bunch going the opposite direction. About 50,000 times a second.
- An antiproton bunch looks pretty much the same as the proton bunch, but there are fewer antiprotons.
- So we collide these things that are about the size of your hair, and they are going at about the speed of light. You'll have to trust me.
- Antiprotons are antimatter. But, unlike Star Trek, we don't just talk about it, we actually make antimatter and use it. For particle physics research.
- When the bunches pass through one another, a few of the protons and antiprotons interact with one another. These matter / antimatter interactions convert some of the energy to mass.
- Remember $E=mc^2$? That's what really happens. Right over there and there.

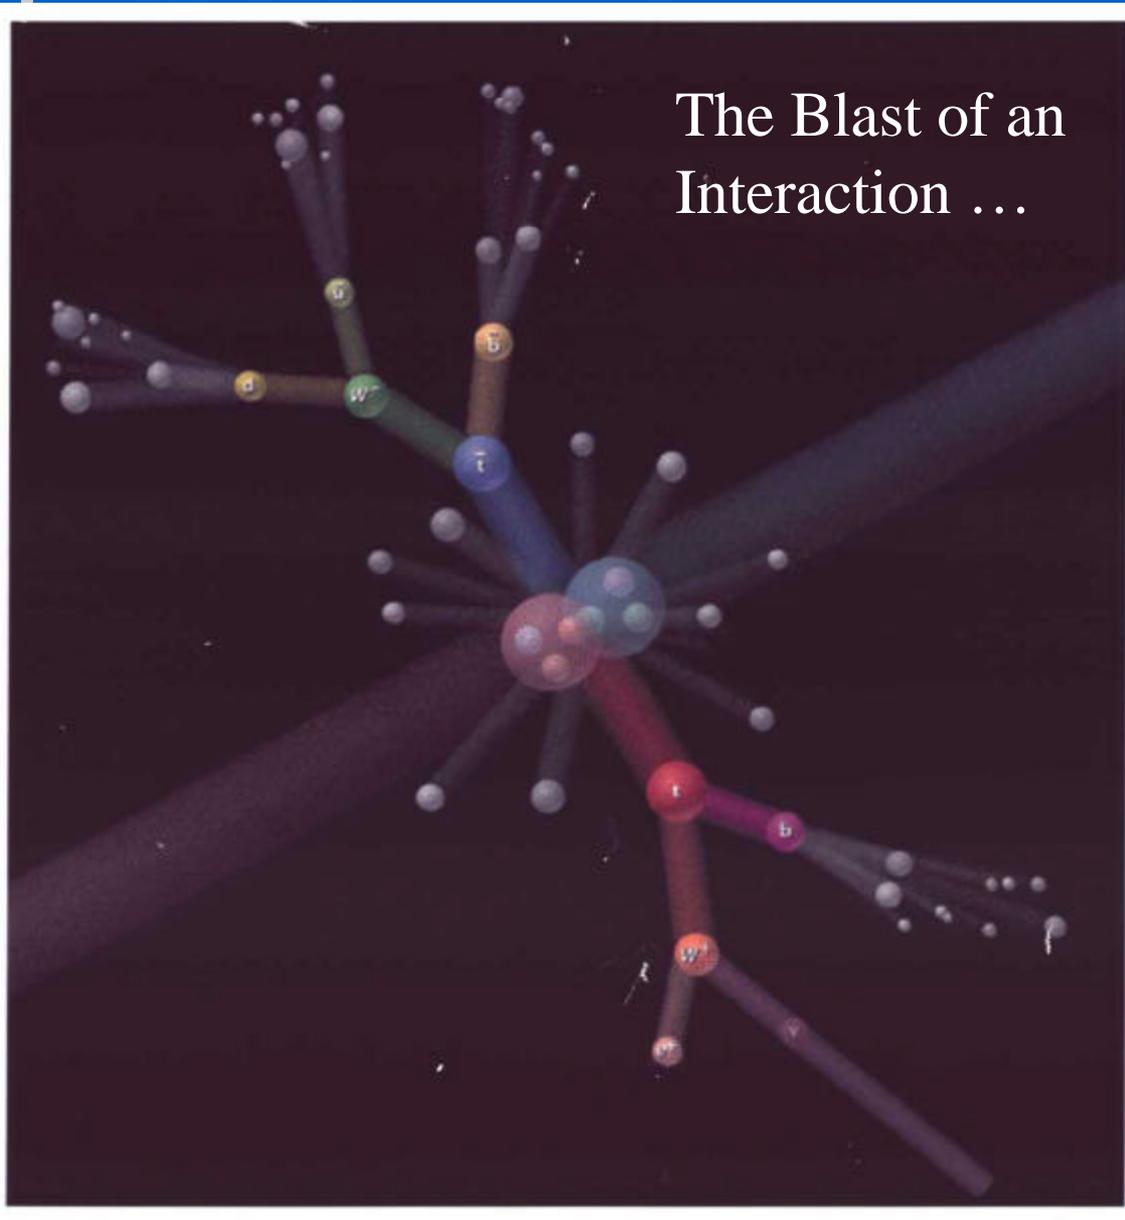

f

Overheard on the 15th Floor - 4

- And sometimes, not very often, an interaction converts the energy to mass in the form of a top quark. And an anti-top quark. Made right here at Fermilab in the Tevatron. And detected right over there in those orange and blue buildings.
- But we really use 36 bunches distributed around the Tevatron. But as we increase the performance of the Tevatron, we will have to start using about 100 bunches in each beam.
- That way we can have more collisions per second, but not many more interactions per bunch crossing. Too many interactions per crossing makes it hard on CDF and D-Zero.
- And it really works.
- And when you get this complex running, you run it 24/7. And pretty much 365. For several years.
- I've been here for about 28 years, and it still amazes me.

f

The Blast of an Interaction ...

- Protons and antiprotons (really quarks, antiquarks, gluons, sea) come in with kinetic energy ...
- $E = mc^2$... and ...
- Lots and lots of new particles come out ...
- And the standard model rules! (So far.)

RHIC

Daily Status Report for June 13

Success!

Last night two experiments (STAR and PHOBOS) measured beam-beam collisions at $\gamma=30$.

We will continue to work on steering at the IP's with colliding beams.

June 13, 2000 PRESS RELEASE**Relativistic Heavy Ion Collider (RHIC) Begins Smashing Atoms**

Experiments will yield insights into the structure of matter and how the universe evolved

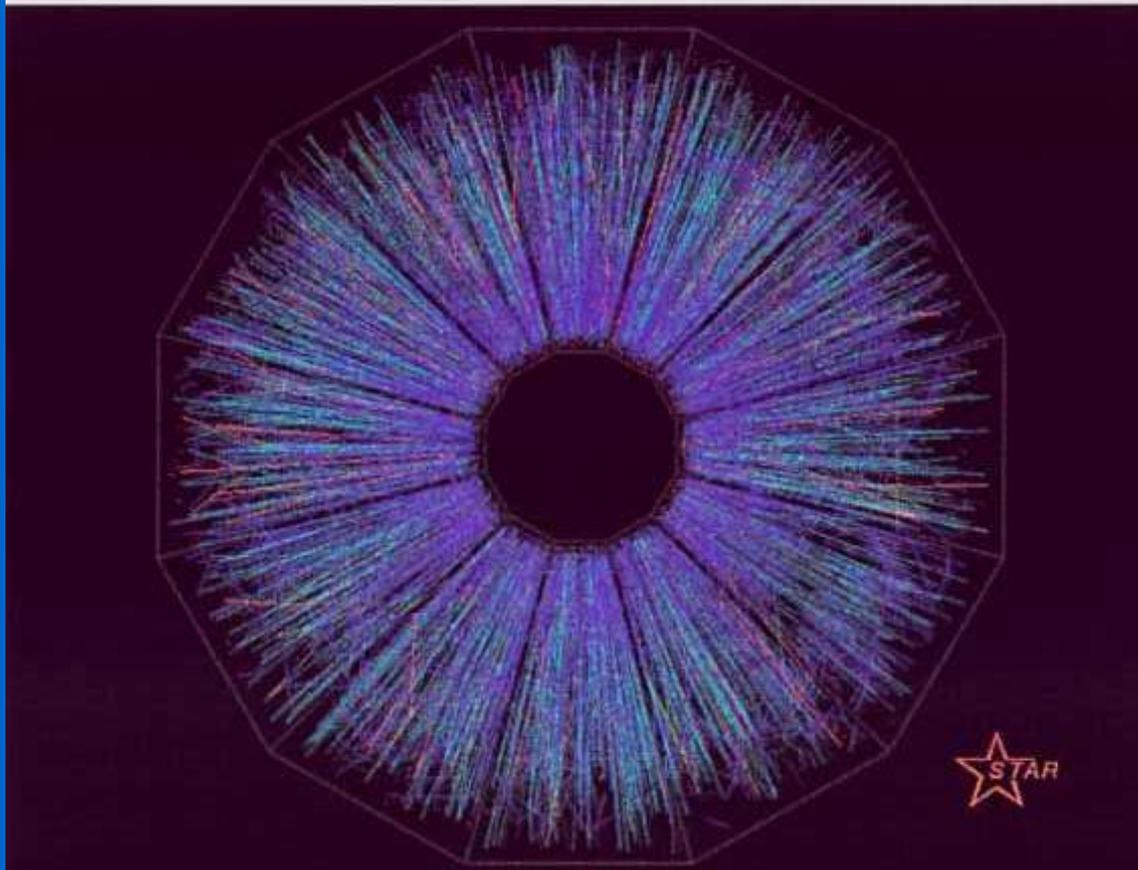

UPTON, NY - Scientists at the U.S. Department of Energy's Brookhaven National Laboratory have begun detecting head-on collisions between gold nuclei in the Relativistic Heavy Ion Collider (RHIC), the world's newest and biggest particle accelerator for studies in nuclear physics. While the beams have been in collision mode since the weekend of June 10, the first spectacular images of particles streaming from a collision point - the definitive evidence the scientists were waiting for - were produced by the STAR detector last night at 9 p.m. High-energy collisions were also seen by the PHOBOS detector early this morning.

Last updated 6/13/00 by [Public Affairs](#)

- RHIC is on Long Island in New York.

Ions ... nuclei ...
GOLD no less!

beams

$E = m c^2$ lives!

This is the view along the beam line

Side View of STAR at RHIC

f

Same as previous slide but seen from the side

Try to figure out what's going on here!

Remember the detector talk?

f

CERN

The CERN accelerator is 26 kilometers in circumference

Near Geneva on the Swiss / French Border

LEP (Large Electron Positron collider) turned off in 2000 with a “hint of a Higgs” ... no discovery.

The LHC will collide a pair of 7 TeV proton beams starting in about 2006 or so

f

DESY (Deutsches Elektronen-Synchrotron)

The HERA accelerator is about
6.3 km in circumference

Partly under the town
of Hamburg, Germany

HERA's superconducting
magnets are very similar to
those in the Tevatron

HERA collides electron
beams with proton beams

f SLAC (Stanford Linear Accelerator Center)

The SLAC linac is about 4 km long.

Goes under I-280 outside Palo Alto, California.

50 GeV electrons.

“linear collider” demonstration

B quark factory.

“Partons”, Charm quark,
Tau lepton

f

Three Magnets ... Three Purposes

Quadrupole Dipole Sextupole

Dipole deflects all particles the same onto the closed orbit.

Quadrupole focuses particles towards the closed orbit in one plane ... and defocuses in the other plane.

Sextupole is used to focus off-energy particles harder than on-energy particles.
