Lecture 2
or
Symplectic mappings of the plane

Tim Zolkin, Sergei Nagaitsev

Winter 2019 USPAS Session
zolkin@fnal.gov

January 29, 2019
0. Why are we interested in discrete time dynamics?

Reduction of a continuous-time systems (flows)

- Poincaré section
- Stroboscopic section of periodically forced systems
- Stroboscopic section of repetitive systems

Solving (or approximating) continuous-time systems

- Numerical integrators (i.e. symplectic integrators)
1. Basic definitions

Map composition is a sequence of consecutive applications of mappings denoted by \( \circ \) operation

\[
f(g(\ldots(h(\zeta))\ldots)) = f \circ g \circ \ldots \circ h(\zeta)
\]

- **Associativity**
  \[
  (f \circ g) \circ h = f \circ (g \circ h) = f \circ g \circ h.
  \]

- **Non-commutativity**
  \[
  f \circ g \neq g \circ f.
  \]

  If \( f \circ g = g \circ f \), mappings \( g \) and \( f \) are said to *commute*.

- **Inverse of a composition**
  \[
  (f \circ g)^{-1} = g^{-1} \circ f^{-1}.
  \]

- **\( n \)-th iterate of the map**
  \[
  f^n(\zeta) = f(f^{n-1}(\zeta)) = f \circ f^{n-1}(\zeta), \quad \text{with} \quad f^0(\zeta) = \zeta.
  \]
Consider a mapping (sometimes, or perhaps always, shortened for map) $T : M \rightarrow M$ defined by a function $f$

$$\zeta_{n+1} = f(\zeta_n), \quad \zeta_i \in M.$$ 

Manifold $M$ can be $\mathbb{R}^n$, $\mathbb{C}^n$, $\mathbb{S}^n$ or $\mathbb{T}^n$.

The trajectory of $\zeta_0$ is the finite set

$$\{\zeta_0, T(\zeta_0), T^2(\zeta_0), \ldots, T^n(\zeta_0)\}$$

The orbit of $\zeta_0$, $M_{\zeta_0} \in M$, is a set of all points that can be reached by iterations

$$\{\ldots, T^{-2}(\zeta_0), T^{-1}(\zeta_0), \zeta_0, T(\zeta_0), T^2(\zeta_0), \ldots\}$$

The $n$-cycle (or periodic orbit of period $n$) is a solution of

$$T^n(\zeta_0) = \zeta_0$$
2. Jacobian of transformation

Jacobian matrix, $J_{i,j} = \frac{\partial f_i}{\partial x_j}$.

$2 \times 2$:

\[
J = \begin{bmatrix}
\frac{\partial q'}{\partial q} & \frac{\partial q'}{\partial p} \\
\frac{\partial p'}{\partial q} & \frac{\partial p'}{\partial p}
\end{bmatrix}
\]

$4 \times 4$:

\[
J = \begin{bmatrix}
\frac{\partial x'}{\partial x} & \frac{\partial x'}{\partial px} & \frac{\partial x'}{\partial y} & \frac{\partial x'}{\partial py} \\
\frac{\partial px'}{\partial x} & \frac{\partial px'}{\partial px} & \frac{\partial px'}{\partial y} & \frac{\partial px'}{\partial py} \\
\frac{\partial y'}{\partial x} & \frac{\partial y'}{\partial px} & \frac{\partial y'}{\partial y} & \frac{\partial y'}{\partial py} \\
\frac{\partial py'}{\partial x} & \frac{\partial py'}{\partial px} & \frac{\partial py'}{\partial y} & \frac{\partial py'}{\partial py}
\end{bmatrix}
\]
3. Symplectic condition

\[ T^T \cdot \Omega \cdot T = \Omega \]

\[ \Omega = \begin{bmatrix} 0 & I_n \\ I_n & 0 \end{bmatrix} \quad \text{or} \quad \Omega = \begin{bmatrix} 0 & 1 & & 0 \\ -1 & 0 & & 0 \\ & & \ddots & \vdots \\ 0 & & 0 & 1 \\ -1 & 0 & & \end{bmatrix} \]

with \( \Omega^{-1} = \Omega^T = -\Omega \).
4. Local Stability

\[ 2 \times 2 \]

**Fixed points**

\[-2 < \text{Tr} J(\zeta_f) < 2 \]

**n-cycles**

\[-2 < \text{Tr} J(\zeta^{(n)}) < 2 \]

where

\[ J(\zeta^{(n)}) = J(\zeta_n^{(n)}) \cdot J(\zeta_{n-1}^{(n)}) \cdot \ldots \cdot J(\zeta_2^{(n)}) \cdot J(\zeta_1^{(n)}) \]

**Higher dimensions**

Look for all eigenvalues of \( J \).
5. Example 1: Kicked rotator

\[ H[p, q, t] = \frac{p^2}{2} + K \cos(q) \sum_{n=-\infty}^{\infty} \delta(t - n) \]

\[ p_{n+1} = p_n + K \sin(\theta_n) \]

\[ \theta_{n+1} = \theta_n + p_{n+1} \]
6. Example 2: Standard map/Chirikov-Taylor map/Chirikov standard map

\[ \Delta E_{n+1} = \Delta E_n + e V (\sin \phi_n - \sin \phi_s) \]

\[ \phi_{n+1} = \phi_n + \frac{2\pi \hbar \eta}{\beta^2 E} \Delta E_{n+1} \]
7. Example 3: Hénon quadratic map
8. Example 4: Gingerbreadman map
We will consider area-preserving mappings of the plane

\[ q' = q'(q, p), \]
\[ p' = p'(q, p), \]
\[ \text{det} \begin{bmatrix} \frac{\partial q'}{\partial q} & \frac{\partial q'}{\partial p} \\ \frac{\partial p'}{\partial q} & \frac{\partial p'}{\partial p} \end{bmatrix} = 1. \]
The reflection is anti area-preserving transformation, \( \det J = -1 \).

In addition, \( \text{Ref}^2 = \text{Id} \) (or \( \text{Ref} = \text{Ref}^{-1} \)). Transformations which satisfy this property are called *involutions*.

**More on reflections and rotations**

\[
\begin{align*}
\text{Rot}(\theta) \circ \text{Rot}(\phi) &= \text{Rot}(\theta + \phi) \\
\text{Ref}(\theta) \circ \text{Ref}(\phi) &= \text{Rot}(2[\theta - \phi]) \\
\text{Rot}(\theta) \circ \text{Ref}(\phi) &= \text{Ref}(\phi + \frac{1}{2}\theta) \\
\text{Ref}(\phi) \circ \text{Rot}(\theta) &= \text{Ref}(\phi - \frac{1}{2}\theta)
\end{align*}
\]
A map $T$ in the plane is called *integrable*, if there exists a non-constant real valued continuous functions $K(q, p)$, called *integral*, which is invariant under $T$:

$$\forall (q, p) : \quad K(q, p) = K(q', p')$$

where primes denote the application of the map, $(q', p') = T(q, p)$.

**Example.** Rotation transformation

$$\text{Rot}(\theta) : \quad q' = q \cos \theta - p \sin \theta$$
$$p' = q \sin \theta + p \cos \theta$$

has the integral $K(q, p) = q^2 + p^2$. 
If $\theta$ and $\pi$ are commensurable, then transformation $\text{Rot}(\theta)$ has infinitely many invariants of motion.

**Example.** Rotations through angles $\pm \pi/4$ has another invariant

$$K(q, p) = q^2 p^2 + \Gamma(q^2 + p^2), \quad \forall \Gamma.$$
Thin lens transformation, $F$, and nonlinear vertical shear, $G$,

\[
\begin{align*}
F : & \quad q' = q, \\
p' &= p + f(q),
\end{align*}
\]

\[
\begin{align*}
G : & \quad q' = q, \\
p' &= -p + f(q),
\end{align*}
\]

\[
F = G \circ \text{Ref}(0),
\]

\[
G = F \circ \text{Ref}(0).
\]

Transformation $G$ is anti area-preserving involution, $G^2 = \text{Id}$. 
A map $T$ is said to be *reversible* if there is a transformation $R_0$, called the *reversor*, such that

$$T^{-1} = R_0 \circ T \circ R_0^{-1}.$$ 

In the important special case, where $R_0$ is involutory

$$T^{-1} = R_0 \circ T \circ R_0 \quad \text{or} \quad R_0 \circ T \circ R_0 \circ T = \text{Id}.$$ 

Hence, if we set $R_1 = R_0 \circ T$, we see that $R_1$ is also involutory. Moreover we have

$$T = R_0 \circ R_1 \quad \text{or} \quad T^{-1} = R_1 \circ R_0$$

so that $T$ is the product of two involutory transformations.
Arnold-Liouville theorem

Integrable map can be written in the form of a Twist map

\[ J_{n+1} = J_n, \]
\[ \theta_{n+1} = \theta_n + 2\pi \nu(J) \mod 2\pi, \]

where \(|\nu(J)| \leq 0.5\) is the rotation number, \(\theta\) is the angle variable and \(J\) is the action variable, defined by the mapping \(T\) as

\[ J = \frac{1}{2\pi} \oint p \, dq. \]

Poincaré rotation number

Rotation number represents the average increase in the angle per unit time (average frequency)

\[ \nu = \lim_{n \to \infty} \frac{T^n(\theta) - \theta}{n}. \]
Theorem (Danilov)

Let $T : \mathbb{R}^2 \to \mathbb{R}^2$ be the area-preserving integrable map with invariant of motion $\mathcal{K}(q, p) = \mathcal{K}(q', p')$. If constant level of invariant is compact, then a Poincaré rotation number is

$$
\nu = \int_{q}^{q'} \left( \frac{\partial \mathcal{K}}{\partial p} \right)^{-1} dq \Bigg/ \oint \left( \frac{\partial \mathcal{K}}{\partial p} \right)^{-1} dq
$$

where integrals are assumed to be along invariant curve.
I. Contribution of Edwin McMillan

From “A problem in the stability of periodic systems” (1970)

In the Spring of 1967 I attended a theoretical seminar at which Professor René de Vogelaere spoke concerning the stability of non-linear periodic systems. The motivation was storage rings, with beams focused by azimuthally varying fields (“strong focusing”); the question, the effect of non-linear terms on an otherwise stable system; the presentation I found utterly fascinating. It recalled another seminar I attended at Princeton* over a third of a century earlier, at which G. D. Birkhoff discussed the stability of the solar system. I remember none of the detail of that earlier seminar, but I have a strong memory of how an apparently simple situation led rapidly and unavoidably into a maze of complexity, leaving the original question “Is the motion of the system stable for infinite time?” unanswered.
McMillan considered a special form of the map

\[
\begin{align*}
M : & \quad q' = p, \\
& \quad p' = -q + f(p),
\end{align*}
\]

where \( f(p) \) is called *force function* (or simply *force*).

a. Fixed point

\[
p = q \cap p = \frac{1}{2} f(q).
\]

b. 2-cycles

\[
q = \frac{1}{2} f(p) \cap p = \frac{1}{2} f(q).
\]
1D accelerator lattice with thin nonlinear lens, \( T = F \circ M \)

\[
M : \begin{bmatrix} y' \\ \dot{y} \end{bmatrix} = \begin{bmatrix} \cos \Phi + \alpha \sin \Phi & \beta \sin \Phi \\ -\gamma \sin \Phi & \cos \Phi - \alpha \sin \Phi \end{bmatrix} \begin{bmatrix} y \\ \dot{y} \end{bmatrix},
\]

\[
F : \begin{bmatrix} y' \\ \dot{y} \end{bmatrix} = \begin{bmatrix} y \\ \dot{y} \end{bmatrix} + \begin{bmatrix} 0 \\ F(y) \end{bmatrix},
\]

where \( \alpha, \beta \) and \( \gamma \) are Courant-Snyder parameters at the thin lens location, and, \( \Phi \) is the betatron phase advance of one period.

Mapping in McMillan form after CT to \((q, p)\), \( T = \tilde{F} \circ \text{Rot}(-\pi/2) \)

\[
q = y,
\]

\[
p = y \left( \cos \Phi + \alpha \sin \Phi \right) + \dot{y} \beta \sin \Phi,
\]

\[
\tilde{F}(q) = 2q \cos \Phi + \beta F(q) \sin \Phi.
\]
Polynomial approximations of symplectic dynamics and richness of chaos in non-hyperbolic area-preserving maps

Dmitry Turaev

Recommended by C Liverani

Abstract
It is shown that every symplectic diffeomorphism of $R^{2n}$ can be approximated, in the $C^\infty$-topology, on any compact set, by some iteration of some map of the form $(x, y) \mapsto (y + \eta, -x + \nabla V(y))$ where $x \in R^n$, $y \in R^n$, and $V$ is a polynomial $R^n \to R$ and $\eta \in R^n$ is a constant vector. For the case of area-preserving maps (i.e. $n = 1$), it is shown how this result can be applied to prove that $C^r$-universal maps (a map is universal if its iterations approximate dynamics of all $C^r$-smooth area-preserving maps altogether) are dense in the $C^r$-topology in the Newhouse regions.
a. Consider a decomposition of map in McMillan form

\[ T = F \circ \text{Rot}(-\pi/2) = G \circ \text{Ref}(0) \circ \text{Rot}(-\pi/2) = G \circ \text{Ref}(\pi/4). \]

b. Lines \( p = q \) and \( p = f(q)/2 \) are sets of fixed points for reversors.

c. If \( \mathcal{K}(q, p) \) is invariant under transformation \( T \), then it is invariant under both, \( \text{Ref}(\pi/4) \) and \( G \):

\[ \mathcal{K}(q, p) = \mathcal{K}(p, q), \quad \mathcal{K}(q, p) = \mathcal{K}(q, -p + f(q)). \]

d. Solving for \( p = \Phi(q) \) from the invariant \( \mathcal{K}(q, p) = \text{const} \)

\[ f(q) = \Phi(q) + \Phi^{-1}(q). \]
Example. Hénon map, \( f(p) = 2 \, p^2 \).

Hénon map

\[
M : \quad q' = p, \quad p' = -q + 2 \, p^2.
\]

Symmetry lines:

\[
p = q, \quad p = q^2.
\]

Fixed points:

\[
(0, 0), \quad (1, 1).
\]
II. Suris theorem and recurrence $x_{n+1} + x_{n-1} = f(x_n)$.

**THEOREM.** Equation (1) has a nontrivial symmetric integral of the form

$$
\Phi(x, y, \varepsilon) = \Phi_0(x, y) + \varepsilon \Phi_1(x, y),
$$

holomorphic in the domain $|x - y| < \delta_0$, in the following and only in the following three cases:

a) $F(x, \varepsilon) = (A + Bx + Cx^2 + Dx^3)/(1 - \varepsilon (E + Cx/3 + Dx^2/2))$, 

$$
\Phi_0(x, y) = (x - y)^2/2, \quad \Phi_1(x, y) = -A (x + y)/2 - B xy/2 - C xy (x + y)/6 - D x^3/4 - E (x - y)^2/2.
$$

b) $F(x, \varepsilon) = \frac{2}{\omega \varepsilon} \arctg \left\{ \frac{\omega \varepsilon}{2} \left( A \sin \omega x + B \cos \omega x + C \sin 2\omega x + D \cos 2\omega x \right) \right\} /
\left\{ 1 - \frac{\omega \varepsilon}{2} \left( A \cos \omega x - B \sin \omega x + C \cos 2\omega x - D \sin 2\omega x + E \right) \right\}$,

$$
\Phi_0(x, y) = (1 - \cos \omega (x - y))/\omega^2, \quad \Phi_1(x, y) = (A (\cos \omega x + \cos \omega y) - B (\sin \omega x + \sin \omega y) + C \cos \omega (x + y) - D \sin \omega (x + y) + E \cos \omega (x - y))/2\omega.
$$

b) $F(x, \varepsilon) = \left( \frac{1 + \alpha x - \alpha y}{\alpha} \right) \left( \frac{B \exp (-\alpha x) + D \exp (-2\alpha x) - E}{1 - \alpha x \exp (\alpha x) + C \exp (2\alpha x) + E} \right)$,

$$
\Phi_0(x, y) = (\sinh \alpha (x - y) - 1)/\alpha^2, \quad \Phi_1(x, y) = (-A (e^{\alpha x} + e^{\alpha y}) + B (e^{-\alpha x} + e^{-\alpha y}) - C e^{\alpha (x+y)} + D e^{-\alpha (x+y)} - 2E \cosh (x - y))/2\alpha.
$$

A Periodic Homeomorphism of the Plane

MORTON BROWN  University of Michigan, Ann Arbor, Michigan

\[ q' = p, \quad p' = -q + |p| \]
"When I saw advanced problem 6439, I couldn’t believe that it was ‘advanced’: a result like that has to be either false or elementary!"

"But I soon found that it wasn’t trivial. There is a simple proof, yet I can’t figure out how on earth anybody would discover such a remarkable result. Nor have I discovered any similar recurrence relations having the same property."

"So in a sense I have no idea how to solve the problem properly. Is there an ‘insightful’ proof, or is the result simply true by chance?"
VI. R. Devaney’s Gingerbreadman map, \( f(p) = |p| + 1 \)

A PIECEWISE LINEAR MODEL FOR THE ZONES OF INSTABILITY OF AN AREA-PRESERVING MAP

Robert L. DEVANEY*

Department of Mathematics, Boston University, Boston, Mass. 02215, USA

Received 14 March 1983

In this note we study the global behavior of the piecewise linear area-preserving transformation \( x_i = 1 - y_{i-1} + |x_{i-1}|, \ y_i = x_{i-1} \) of the plane. We show that there are infinitely many invariant polygons surrounding an elliptic fixed point. The regions between these invariant polygons serve as models for the “zones of instability” in the corresponding smooth case. For our model we show that some of these annular zones contain only finitely many elliptic islands. The map is hyperbolic on the complement of these islands and hence exhibits stochastic behavior in this region. Unstable periodic points are dense in this region.

Fig. 2. 10,000 iterates of a single point in the region \( A_i \). The inner boundary of \( A_i \) is the outer boundary of \( B_0 \).

Fig. 3. The outer region is the ergodic region \( B_i \); the inner region is \( B_0 \) as shown in fig. 1.
Gingerbreadman and Rabbit maps

\[ q' = p \]
\[ p' = -q \pm |p| + 1 \]
V. Lozi and Hénon maps

\[ M_L : \begin{align*}
q' &= p \\
p' &= b q + 1 - a |p|
\end{align*} \]

\[ M_H : \begin{align*}
q' &= p \\
p' &= b q + 1 - a p^2
\end{align*} \]
